Deploy a containerized web app on ECS Fargate using Terragrunt for two environments: dev + prod

Requirements:

- PLAN only -- no need to host/deploy it anywhere, but make it ready to be used (backend config etc.) so i could test it / plan it
- One reusable module for `ecs-service` -- unless u have a different idea to tackle the code for this
- App reads one secret from secrets manager
- App connects to Redis Elasticache replication group (no code for redis required) just ensure with fake connectivity towards redis that it would reach it and why (networking, security etc..)
- Add autoscaling based on your idea to scale it, if app is memory or cpu oriented or something else
- Make prod different from dev (HA, scaling, etc)
- README covering whats provided + trade-offs + "what would i add more later or with more time"
- Image/app is irrelevant, u can host nginx or whatever u want (go crazy)

solution should be placed on a public GIT repo, available prior the interview so we can get familiar with it.
